

# Instrument Processing: Corrections Summary

7 oral presentations and 7 poster presentations

Covered radiometer wet tropospheric correction, sea state bias correction  
and flags

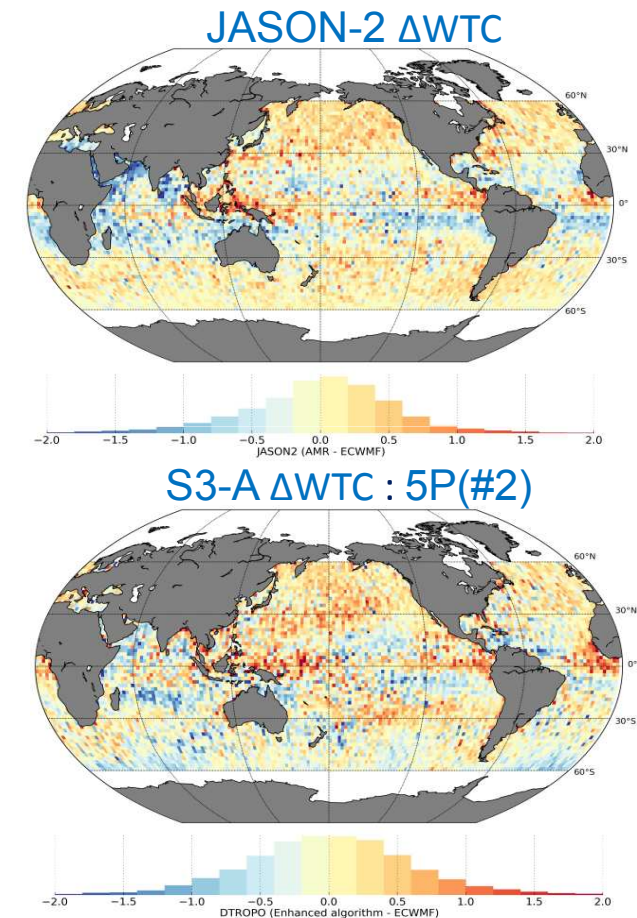

# Jason-3 AMR Performance Assessment

- Jason-3 AMR performing well
  - Jason-2 and Jason-3 producing identical PDs to within 3mm
- Jason-3 is experiencing a noise diode drift which is removed using the cold sky calibrations and the vicarious cold reference (ocean)

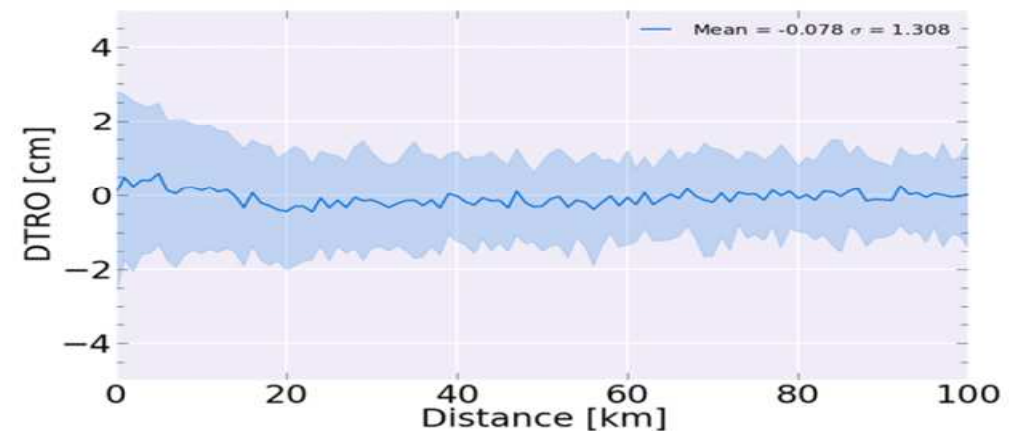

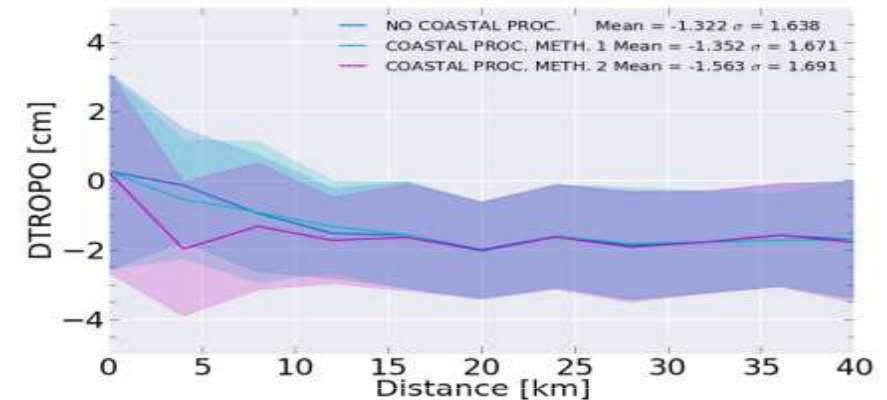

# Sentinel-3 MWR Performance Assessment

- Very good performances of S3A/MWR since switch-on:  
Global good agreement with other radiometers
  - Good performances for hottest BTs
  - Lowest Bts are cooler than other MWR, the new set of calibration parameters address the issue
- Assessment of wet tropospheric correction
  - Good performances on the wet tropospheric correction for both new NN algorithms
- Perspectives
  - New radiometer calibration timeline to reduce data gaps in L2 products

# Future Microwave Radiometers for Atmospheric Correction

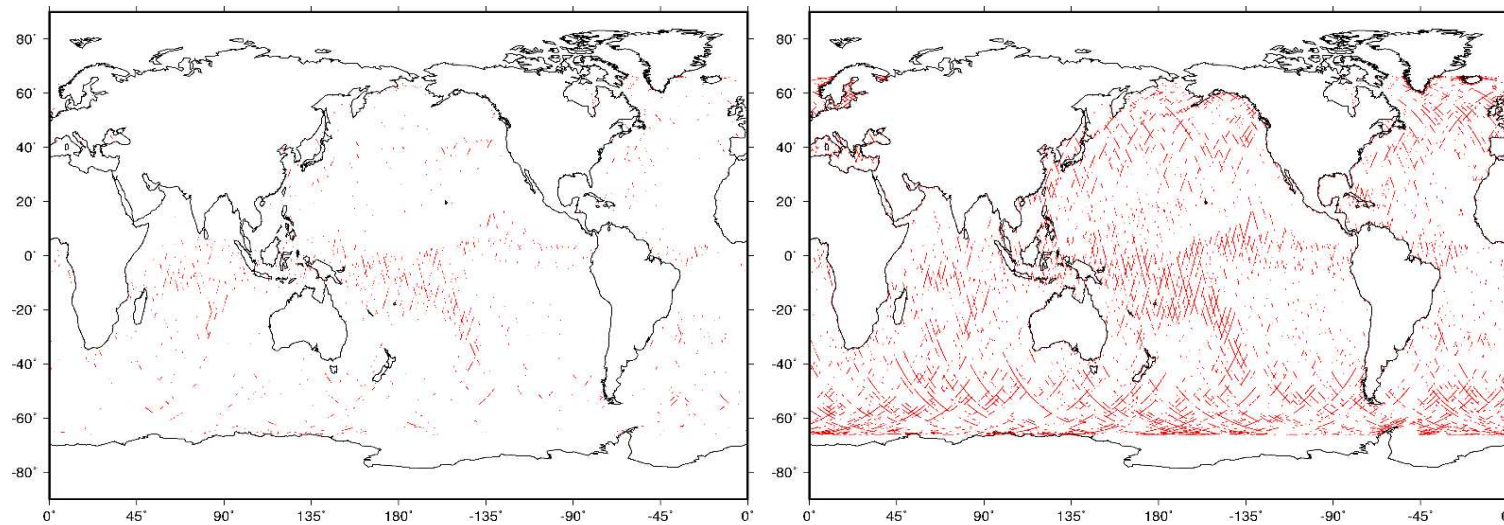

- Study to evaluate new optimized instrument design and retrieval algorithms for wet tropospheric correction
  - Focused on improvement in coastal areas, using benefit from high-frequency channels
- Optimized radiometer
  - Channel selection based on retrieval performance and instrument design constraints (e.g. cost, feasibility, resources)
  - 23.8, 36.5 50.3, 53.596, 89, 183+/-11 GHz
- Combination of high-frequency channels and 1D-var approach promise to the capability to downscale retrievals not limited by instrument resolution

# Improvements to rain flag

- Several issues identified with current implementation of Jason-3 rain flag, resulting in an anomalously large number of flagged values
  - Rain flag seemed to be based only on CLW
  - There are biases between expected values from lookup table (LUT) vs. measured values of  $s_0$
  - The rain flag is set when  $rad\_surf\_type > 0$  (coastal zones) &  $qual\_alt\_1hz\_ku > 0$
- Corrected algorithm resulted in more reasonable amount of flagged values
  - Future improvements could consider SST dependence of differential backscatter at Ku and C-bands for more accurate flagging

Jason-3 OGDRs: 2016/02/12-22

Corrected Rain Flag

Preliminary Rain Flag

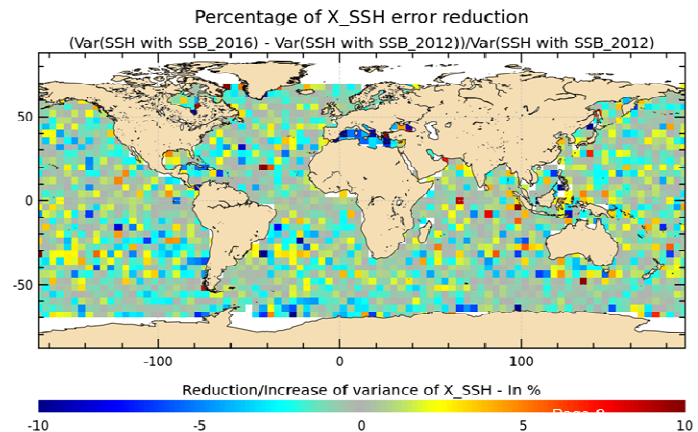

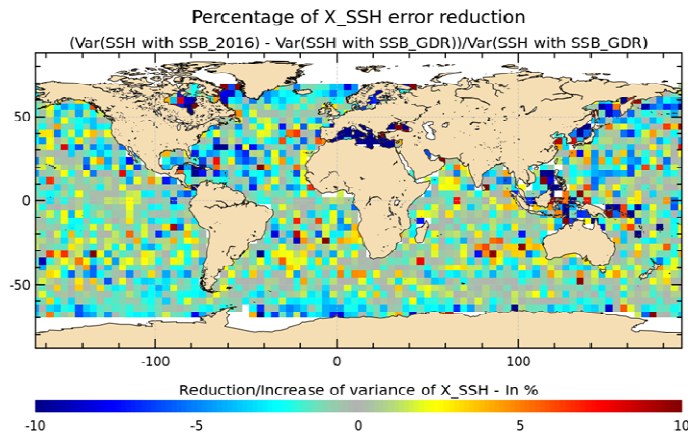

# Consistent set of SSB models for reference missions

- Comparison of various SSB models with UPORTO SSB model
- For Topex and Jason-1, the validation of UPORTO SSB model is in line with the standard SSB models currently available
- The proposed approach is capable of generating a reliable model with a limited training dataset (20 cycles)
- For Jason-2 and -3 the proposed model achieves a reduction of SLA variance in 1% when compared with standard SSB models

# Improvements to Jason-3 SSB Correction

- Preliminary Jason-3 SSB models (2D and 3D) have been computed, will be re-computed after 1-year of GDR data
- Alternate 3D SSB models derived from collinear SSH differences have been computed and show some differences with standard 3D models derived from SLA data; further comparisons are needed.

# Roundtable Discussion/Recommendations (1 of 2)

- **Jason-2 cold sky maneuvers**

- Cold sky maneuvers have proved valuable for Jason-3 and **should be continued for Jason-2, at least for inter-leaved mission**
  - Provide data to stabilize long term record
  - Provide additional insight into calibration behavior which may benefit first 8 yrs of mission

- **Change in GDR production schedule allowing up to 90-day latency for optimal use of cold sky data**

- **Proposal fully supported by IPC**
  - Best quality product, lower potential for large changes to GDR later on
  - Having the best possible calibration on GDR extends time between reprocessing
  - All GDRs have equal uncertainty, instead of some having higher uncertainty
  - Median latency only changes +5 days (65 days compared to 60) – user community input from other splinters

## Roundtable Discussion/Recommendations (2 of 2)

- **Calibrator for Sentinel-6 (Jason-CS)**

- IPC supports long term stability requirement and need for calibrator on Sentinel-6
  - Thanks to the project for seeking OSTST comment on this important issue
  - Radiometer calibration is largest source of error in measured GMSL trend – new requirement for stability on Sentinel-6 ensures stable measurement for next decade
  - Radiometer design for Sentinel-6, which includes calibrator and new risk compared to Jason-2/3, will still meet equivalent reliability standards as other operational instruments, including prior Jason radiometers
  - Risk of failure no different than any other part on spacecraft (all components meet operational reliability requirements)
